Acetaminophen toxicity is the most common cause of acute liver failure (ALF) and death in the United States. Identification of the patients at highest risk for this severe event will facilitate earlier treatment. We determined the clinical and molecular features of 49 patients with ALF due to acetaminophen intoxication. The median age was 36 years (range: 2-75), and females were predominant (60.5%). Seventy-eight percent had advanced fibrosis or cirrhosis. The median time between ingestion of the last dose of acetaminophen and diagnosis of ALF was 15.5 hours. The mean Model for End-Stage Liver Disease score at admission was 28.9 (range: 11-46). Acute liver failure was severe, with 80% requiring dialysis, 63% receiving mechanical ventilation, and 59% receiving vasopressors. The median Acute Physiology and Chronic Health Evaluation II score at admission was 21 (range: 12-32). On admission, 80% had creatinine levels of 1.5 mg/dL or greater. During the course of the disease, 15 patients died, with the most frequent cause of death being multisystem organ failure (63%). Multiple organ failure (82%), renal failure (60%), and sepsis (60%) were the most common causes of death. Early death was associated with Model for End-Stage Liver Disease score >20 (P =.01), renal failure (P a1d647c40b
