Because of its layered structure, polycrystalline molybdenum disulfide (MoS₂) has been considered to have a low electrical conductivity, which makes it difficult to be utilized as electrode material for lithium ion batteries (LIBs) and supercapacitors. To improve the conductivity of MoS₂, sulfur-deficient MoS₂ layers can be formed and the conductivity can be enhanced. The formation of such sulfur-deficient MoS₂ layers can be realized by Ar plasma treatment, acid solution treatment, and the combination of these two treatments (as a sulfur-deficient polycrystalline MoS₂ electrode; CDPC-MoS₂). By using in situ X-ray photoelectron spectroscopy, the electronic structure of the CDPC-MoS₂ and its relationship to the electrical conductivity were characterized in detail. It was found that the sulfur-deficient MoS₂ layer contains a small amount of oxygen- or nitrogen-containing groups, which result in an expanded band gap. Moreover, the concept of conducting channels was established to explain the increased conductivity of the CDPC-MoS₂. Such a method can be utilized to fabricate a variety of sulfur-deficient MoS₂ electrodes. The results suggest that this technique can be applied to various electrodes in electronic devices and energy-related areas.Hexagram 5 - Delicate 1 \$350.00 \$180.00Save: 35% off What is the meaning and indication of the Hexagram 5 - Delicate?
